Example Retail Ltd: your questions answered

Is our code converted?

2 of 7 items are converted, and each was checked by running it against your original on test data, then checked again by an independent second check.

What is not converted yet, and why?

- **Moves orders older than a cut-off date into the archive tables.**: Failed: completeness. 3 rows that should have been archived were left behind.
- **Applies a staged price list to the product table.**: Failed final validation.
- **Summarises an order for the confirmation e-mail.**: Blocked by sales.uspArchiveOrders.

We are working on these. Nothing is needed from you.

What will a person have to do by hand?

- **Searches product descriptions.**: Full-text search (CONTAINS) is not supported on Databricks.
- **Nightly load of the day's sales from the till system.**: SSIS packages are recognised and listed, not converted, in v1.

What do you need from us?

- **Extract the database ArchiveDB.** 2 procedures read it; extracting it would make them reconcilable.
- **Export identity starting values at cutover.** Needed so new order numbers continue from the live system's, not from the highest number in the data.

Did you find problems in our current system?

- In the original, monthly totals do not add up to the yearly total when an order is refunded in a later month. The conversion reproduces this.

The converted code behaves the same way, so nothing changes until you decide to fix it.

Is there anything the converted code relies on?

During a run, converted code is the only writer to the tables it writes. Emulated transactions, identity values and constraint checks are correct only while this holds.

What happened to our code during conversion?

It was processed under a zero retention arrangement at Amazon Bedrock. Content never leaves AWS and is never shared with Anthropic.
